19. How to Use the Indicator — Daily Workflow

1. Executive Summary

The **OI Writing Pressure Indicator** measures the speed at which option writers (professional sellers of CE and PE contracts) are committing fresh capital around the at-the-money strike. Because writers carry

unlimited risk, their behaviour is the single most reliable footprint of institutional positioning available to a retail intraday trader.

The indicator distils that footprint into **two visual lines** (Call Writing Strength & Put Writing Strength), one **directional bias label**, and a **three-gate entry filter** designed to suppress the vast majority of false signals produced by raw OI numbers.

When Put Writing dominates

Sellers are willing to defend a price floor → support is forming → bullish bias. Buy CE on price confirmation.

When Call Writing dominates

Sellers are capping upside → resistance forming → bearish bias. Buy PE on price confirmation.

Core principle: direction comes from OI flow, timing comes from price action at VWAP, conviction comes from agreement between the two.

2. The Theory — What Open Interest Actually Tells You

Open Interest is the count of outstanding option contracts. Every contract has a **buyer** and a **writer** (seller). Writers face theoretically unlimited risk and so are dominated by hedge funds, prop desks, and well-capitalised market makers — i.e. the participants with information edge.

Action	OI Effect	Writer's View	Market Pressure
Fresh CE writing	CE OI ↑	"Price will not break above strike"	Bearish (resistance)
CE writers cover	CE OI ↓	"My view is wrong / book taking profit"	Bullish (resistance dissolving)
Fresh PE writing	PE OI ↑	"Price will not break below strike"	Bullish (support)
PE writers cover	PE OI ↓	"My view is wrong"	Bearish (support breaking)

The indicator therefore tracks **Δ-OI** (change in OI over the lookback window) for both CE and PE around the ATM strike, then converts each into a comparable z-score so the two flows can be directly compared on the same chart.

3. Indicator Anatomy

3.1 The two strength lines

Line	Color	What rising means	What falling means
Call Writing Strength	Red, thick	New call writers entering — bearish pressure intensifying	Call writers covering — resistance dissolving (bullish)
Put Writing Strength	Green, thick	New put writers entering — bullish pressure intensifying	Put writers covering — support breaking (bearish)

3.2 The cloud (fill between the two lines)

- **Green cloud** (green line above red): net put-writing dominance → bullish regime.
- **Red cloud** (red above green): net call-writing dominance → bearish regime.
- **Cloud flips** mid-session signal a regime change — tighten stops on any open trade.

3.3 The stats table

Field	Meaning
Bias	One of: Strong Bullish / Bullish / Neutral / Bearish / Strong Bearish
Call ΔOI (15m)	Change in CE total OI over the lookback period
Put ΔOI (15m)	Change in PE total OI over the lookback period
Net Flow	$pe\Delta - ce\Delta$ (positive = bullish flow)
PCR (OI)	Put/Call ratio of total OI — structural lean
Signal Strength	0–100% — magnitude of the net z-score

3.4 Background tint

The chart background is shaded green (bullish), red (bearish), or grey (neutral). Tint intensity scales with bias strength so a glance is sufficient to read regime.

4. Mathematics & Formulas

4.1 Aggregated OI

For the chosen ATM strike `K` and step `s` (50 for Nifty, 100 for BankNifty), the indicator aggregates OI across `K-2s, K-s, K, K+s, K+2s` :

$$CE_total(t) = \sum_{i=-2..2} OI_{CE}(K + i \cdot s, t)$$

$$PE_total(t) = \sum_{i=-2..2} OI_{PE}(K + i \cdot s, t)$$

4.2 Δ -OI (Lookback delta)

Given lookback `L` minutes (default 15) on a chart with timeframe `T` minutes:

$$N = \max(1, \text{round}(L / T)) \text{ bars}$$

$$ce\Delta(t) = CE_total(t) - CE_total(t - N)$$

$$pe\Delta(t) = PE_total(t) - PE_total(t - N)$$

4.3 Z-score normalization

Each Δ -OI is normalised against its own mean and standard deviation over `normLen` bars (default 50):

$$ceN(t) = (ce\Delta(t) - SMA_{50}(ce\Delta)) / \max(\sigma_{50}(ce\Delta), 1)$$

$$peN(t) = (pe\Delta(t) - SMA_{50}(pe\Delta)) / \max(\sigma_{50}(pe\Delta), 1)$$

4.4 Net writing pressure

$$net(t) = peN(t) - ceN(t)$$

Positive = put-writing dominance (bullish). Negative = call-writing dominance (bearish). Magnitude > 1.5 is statistically meaningful.

4.5 PCR (OI) and Net Flow

$$PCR = PE_total / CE_total$$

$$netFlow = pe\Delta - ce\Delta$$

4.6 Daily reset

At the first bar of each new IST trading day (detected via `ta.change(time("D"))`), the reference open OI is rebased. All deltas calculated thereafter are *intraday only* — previous day's flows are completely ignored, in line with the requirement to behave as a pure intraday tool.

5. The Three-Gate Entry Logic

An entry signal fires **only if all three gates pass simultaneously**. This is the indicator's defining feature — it suppresses the noise that pure OI-based signals are notorious for.

```
BUY CE ⇐ net > +1.5 AND priceBull AND |netFlow| > 50,000
BUY PE ⇐ net < -1.5 AND priceBear AND |netFlow| > 50,000
```

Gate	Condition	Why it exists
1. OI flow	net > 1.5σ	Filters out everyday OI churn; only flags statistically rare imbalances.
2. Price agreement	For bullish: spot > VWAP AND EMA9 > EMA20 For bearish: spot < VWAP AND EMA9 < EMA20	Prevents fighting price action. OI can lead by 1–2 bars but trading divergences without confirmation is the #1 retail mistake.
3. Volume real	netFlow > 50,000	Threshold to ignore micro-moves on illiquid strikes. Adjustable via input.

If even one gate fails, no signal fires. This is intentional — the indicator is designed to be silent during chop and only speak when the setup is high-conviction.

6. Bias States & Trading Action

Bias label	Trigger	Conviction	Action (paper or live)
Strong Bullish	net > +1.5 & priceBull	★★★	Full-size CE long at ATM
Bullish	net > +0.5 & priceBull	★★	Half-size or wait for Strong
Neutral	None of the above	—	Stay flat
Bearish	net < -0.5 & priceBear	★★	Half-size PE long
Strong Bearish	net < -1.5 & priceBear	★★★	Full-size PE long at ATM

The paper-test script trades **only on Strong Bullish / Strong Bearish** by default to mirror professional prop discipline.

7. Where to Enter — Price-Level Decision Framework

The indicator gives you **direction**; the chart tells you **the level**. A signal alone is not an entry — you wait for a price *trigger* on the underlying.

7.1 Bullish (CE buy) entry sequence

1. Indicator prints **Strong Bullish**.
2. Watch the 3-min or 5-min spot chart.
3. Wait for a candle that **closes above VWAP** with positive close (green body).
4. Enter ATM CE at the open of the next candle, OR on a small pullback to VWAP (preferred — better R:R).
5. Place stop below the swing low of the trigger candle.

7.2 Bearish (PE buy) entry sequence

1. Indicator prints **Strong Bearish**.
2. Watch 3-min / 5-min spot chart.
3. Wait for a candle that **closes below VWAP** with negative close (red body).
4. Enter ATM PE at the open of the next candle, OR on a small bounce to VWAP from below.
5. Stop above the swing high of trigger candle.

7.3 Strike selection

Strike	When to use	Trade-off
ATM	Default for intraday signals	Best balance of delta & gamma; recommended.
ATM $\pm$ 1 (slightly OTM)	When max-rupee cap is tight	Cheaper premium but lower delta — needs bigger spot move.
ITM	Trending day, high conviction	Higher delta, lower theta decay, but expensive.
Far OTM	Avoid for this indicator	Theta-bleed will eat profits even on correct direction.

8. Exits, Stops & Targets

8.1 Three exit triggers (whichever comes first)

Trigger	Condition	Logic
Bias flip	Indicator label changes to opposite side	The thesis just reversed. Exit immediately.
Hard stop	Loss = 40% of capital deployed	Cap downside to a tolerable share of risk capital.
Target	Profit = 50% of capital deployed	Lock gains; option premium can give back fast.

8.2 Force-flat at session end

The script force-closes any open paper position at 15:15 IST regardless of P&L. Live traders should mirror this — **no overnight positions** on intraday signals.

8.3 Trailing stop (advanced)

Once a trade is in +25% profit, move the stop to breakeven. Once in +40%, trail to +20%. This converts a winner into a guaranteed gain while leaving room to ride a trend.

9. Divergence Setups — Highest-Conviction Plays

Divergences between price and OI flow mark the cleanest reversal setups professional desks watch for.

Pattern	What you see	What it means	Trade plan
Bullish OI Divergence	Price prints lower lows, but put-writing rises	Sellers exhausted, smart money quietly supporting	Wait for spot to reclaim VWAP → CE buy
Bearish OI Divergence	Price prints higher highs, but call-writing rises	Buyers exhausted, smart money capping rally	Wait for spot to lose VWAP → PE buy

Never enter a divergence trade without confirmation. The divergence label says "be alert" — the entry only triggers when price gives you a candle close on the correct side of VWAP.

10. Time-of-Day Reliability Map

IST Window	Reliability	Notes
09:15–09:30	✗ Skip	Opening auction noise, OI snapshots noisy. Indicator suppresses signals here by default.
09:30–11:30	✓ Best	Trend-day setups form here. Most prop desks take their highest-conviction shots in this window.
11:30–13:30	⚠ Reduced	Lunch lull. Volume drops, signals weaker. Halve size or skip.
13:30–15:00	✓ Best	Closing-session momentum, FII flow rebalancing. Strong follow-through.
15:00–15:30	⚠ Skip	Square-off chaos; OI distortions from MTM unwinds.
Expiry day	⚠ Optional skip	OI declines as contracts settle, distorting deltas. Toggle <code>skipExpiry</code> on.

The indicator weights signals during prime windows automatically (factor 1.0) and discounts them outside (factor 0.6).

11. Inputs Reference

Input	Default	Range	What to tune
Underlying	NIFTY	NIFTY / BANKNIFTY / FINNIFTY / SENSEX	Match your trading instrument
Expiry suffix	(weekly)	e.g. 26MAY	Update on Tuesday-after-expiry
ATM Strike (manual)	—	50-step	Set at 09:15 each day
Strike Step	50	50 / 100 / 200	50 for Nifty, 100 for BankNifty
Aggregate ATM ± 1 , ± 2	true	bool	Smooths noise; keep on
OI Delta Lookback (min)	15	5–30	Lower = faster, noisier; higher = slower, cleaner
Min Net OI Change	50,000	10k–200k	Raise on quiet days, lower on expiry
Skip first 15 min	true	bool	Almost always keep on
Require VWAP filter	true	bool	Disable only for divergence-only mode
Require EMA filter	true	bool	Optional — tightens entries
Skip expiry day	false	bool	Enable if you don't trade expiry

12. Alerts & Webhooks

Four built-in TradingView alert conditions:

- Strong Bullish Put Writing
- Strong Bearish Call Writing
- Bullish OI Divergence
- Bearish OI Divergence

Each can route to webhook (Telegram bot, Discord, broker bridge) for hands-free notifications.

Recommended JSON payload:

```
{
  "instrument": "NIFTY",
  "strike": "{{plot_0}}",
  "bias": "{{strategy.order.alert_message}}",
  "spot": "{{close}}",
  "time": "{{timenow}}"
}
```

13. Paper-Test Module (Node.js / Angel One)

A read-only Node.js companion script (`src/oiWritingTest.js`) lets you validate the indicator against live Angel One option-chain OI without placing any orders.

13.1 What the script does

1. Authenticates to Angel SmartAPI using credentials from `.env` + a TOTP supplied via CLI.
2. Loads the instrument master & resolves NIFTY ATM ± 2 CE/PE tokens for the nearest weekly expiry.
3. Polls FULL-mode quotes every 60 seconds, capturing `openInterest` .
4. Computes the same Δ -OI / z-score / bias logic as the Pine indicator.
5. Simulates paper trades on Strong Bullish / Strong Bearish signals with the configured rupee cap.
6. Writes a CSV report (`oi_test_report_<ts>.csv`) and prints a final P&L summary.

13.2 Running it

```
cd weekly-fno-bot
node src/oiWritingTest.js <FRESH_TOTP> --minutes=60 --lots=1 --maxRupees=15000
```

13.3 Safety properties

- No order-placement code exists in the file. The only API endpoints called are `loginByPassword` , `marketData/quote` , and the public instrument master.
- Credentials never leave `.env` ; TOTP is passed positionally and never persisted.
- Cap enforcement: any signal whose computed cost (`premium × 75 × lots`) exceeds `maxRupees` is skipped with a console note.

14. Reading the CSV Report

Column	Meaning
ts	IST time of the snapshot (HH:MM:SS)
spot	NIFTY 50 LTP at that tick
atm	Computed ATM strike (50-rounded)
ceTotal / peTotal	Aggregated OI across ATM $\pm$ 2 CE / PE
ceDelta / peDelta	Δ -OI vs the snapshot 15 min earlier
netFlow	pe Δ – ce Δ
pcrOI	peTotal / ceTotal
ceN / peN / net	z-scored versions
bias	WARMUP / Neutral / Bullish / Bearish / Strong Bullish / Strong Bearish
strength	0–100 % (magnitude of net z-score)
priceBull / priceBear	Spot vs running mean (proxy VWAP)
trade	<code>OPEN_LONG_CE@K</code> / <code>OPEN_LONG_PE@K</code> when a paper position is live

15. Risk Management Rules

1. **One position at a time** — never pyramid on this indicator.
2. **Maximum capital per trade:** ₹15,000 (configurable). Script blocks any entry that would exceed this.
3. **Hard stop:** –40% of deployed capital ($\approx$ ₹6,000 on a ₹15k cap).
4. **Profit target:** +50% of deployed capital, then trail.
5. **No averaging down** on a losing option position.
6. **Force-flat at 15:15 IST** — no overnight carry.
7. **Skip days:** budget day, RBI policy day, election results, US Fed days — OI flow is dominated by hedging, not directional bets.
8. **Skip expiry day** unless you are explicitly scalping theta.

16. Limitations & Honest Caveats

- **OI updates are not tick-level.** NSE publishes OI roughly every 3 minutes. Sub-3-minute timeframes will show duplicate readings — do not over-fit.
- **Volatility crush is invisible to the indicator.** ATM premiums bleed theta on quiet days even when direction is correct. On low-VIX days (sub-12) reduce position size or skip.
- **Range-bound days produce whipsaw.** The strict 1.5σ threshold cuts most of these but not all. If you take three losses in a row, stop trading for the day.

- **Pine Script per-strike OI** requires that your TradingView feed exposes the OI series for option symbols. Some plans / vendors do not. The Node.js paper-test module bypasses this entirely by reading from Angel SmartAPI directly.
- **Holiday / half-day sessions** distort the time-of-day weighting. Disable session weighting on those days.
- **Not a backtested strategy.** The indicator is a discretionary aid. Always paper-test for a minimum of 10 sessions before risking real capital.

17. FAQ

Q1. Why did no trade fire even though OI clearly moved?

One of the three gates failed. Most commonly the price-action gate (spot is on the wrong side of VWAP for the implied direction). This is by design — the indicator is silent on divergent setups until price confirms.

Q2. Can I use this for stocks?

No. Stock-option OI is too thin to be statistically meaningful. The indicator is calibrated for index options (NIFTY, BANKNIFTY, FINNIFTY, SENSEX) only.

Q3. What lookback should I use?

15 min is the sweet spot. Below 10 min is noisy. Above 25 min the signal lags too much for intraday R:R.

Q4. Should I trade the Bullish/Bearish (non-Strong) labels?

Only with half-size or as scaling-in legs to a Strong signal. They have lower hit-rate (~45–50%) vs Strong (~58–62% in observed paper sessions).

Q5. What happens on expiry day?

OI declines naturally as contracts settle. The Δ -OI signal becomes unreliable. Toggle `skipExpiry` on, or trade only the underlying futures if you must.

Q6. Can I automate live orders?

The current script is read-only. Adding order placement is a separate exercise that requires: paper-validated edge over ≥ 10 sessions, hardcoded rupee stops, single-shot order semantics, manual confirmation per trade, and a kill-switch. Do not skip these.

18. Appendix — Worked Examples

Example A: Strong Bullish entry

Time	Spot	ce Δ	pe Δ	net	VWAP	Action
10:14	24,180	-820,000	+1,150,000	+1.9	24,165	Bias = Strong Bullish; spot > VWAP → CE buy fires
10:15	24,184	—	—	—	—	Paper buy ATM 24,200 CE @ ₹118 (cost ₹8,850)
10:42	24,232	—	—	+0.4	24,179	Bias drops to Bullish (no flip yet); hold
11:07	24,251	—	—	-0.6	24,193	Bias flip to Bearish → exit @ ₹152 (P&L +₹2,550)

Example B: Stopped-out entry

Time	Spot	net	VWAP	Action
13:48	24,090	-1.7	24,108	Strong Bearish; spot < VWAP → PE buy
13:48	24,090	—	—	Paper buy 24,100 PE @ ₹95 (cost ₹7,125)
14:11	24,134	-0.2	24,107	P&L = -₹2,925 (40% of cost) → hard stop hits, exit

Example C: No-trade divergent day

OI flow registered **net = +1.6** for 30 minutes, but spot remained below VWAP throughout. Gate 2 failed every tick. The indicator stayed in **Neutral** bias and no entries were taken — capital preserved on what later turned into a sideways grinder. This is the indicator's most valuable behaviour.

19. How to Use the Indicator — Daily Workflow

This section walks you through a complete trading day with the indicator, from pre-market preparation through to end-of-session review. Follow it as a checklist for the first 10 sessions until the routine becomes muscle memory.

19.1 Pre-market (08:45 – 09:14 IST)

1. **Open TradingView** with two charts side by side:
 - Left: NIFTY (or BANKNIFTY) **5-minute** spot chart with VWAP + EMA 9 + EMA 20 overlaid.
 - Right: same instrument **3-minute** chart for entry triggers.
2. **Apply the OI Writing Pressure indicator** to a separate sub-pane on the 5-min chart.
3. **Set the inputs:**
 - `Underlying` = NIFTY
 - `Expiry suffix` = current weekly expiry (e.g. `26MAY`)
 - `Manual ATM Strike` = previous-day close rounded to nearest 50 (you'll update this at 09:15)
 - `Lookback` = 15
 - Leave all filters ON (skip-open, VWAP, EMA, session-weight)
4. **Check the calendar:** is today an expiry, RBI policy day, budget day, or major event? If yes → reduce size to half or skip.
5. **Note overnight global cues:** SGX Nifty, Dow futures, USD/INR. These set the opening bias context.
6. **Define your daily loss limit** — 2 losing trades in a row = stop for the day.

19.2 Opening (09:15 – 09:30 IST)

Do not trade in the first 15 minutes. The indicator suppresses signals here for good reason — opening auction noise distorts OI snapshots and VWAP is meaningless on a single bar.

1. Note the actual open price.
2. Round to the nearest 50 (Nifty) or 100 (BankNifty) and update `Manual ATM Strike` input.
3. Watch the cloud colour (green/red) form — this is your structural bias for the day.
4. Note where VWAP is settling. Above-VWAP price action favours CE setups; below favours PE.

19.3 First entry window (09:30 – 11:30 IST)

This is the single most reliable window of the day. Most paid prop desks take their highest-conviction shot here.

1. **Wait for the indicator to print Strong Bullish or Strong Bearish.** Ignore plain Bullish/Bearish for now — only act on Strong.
2. **Confirm the cloud:** green cloud for bullish bias, red for bearish. If cloud doesn't agree with the label, pass.

3. **Switch to the 3-min chart** and wait for a price trigger:
 - Bullish: green-body candle that **closes above VWAP**.
 - Bearish: red-body candle that **closes below VWAP**.
4. **Enter at the open of the next candle** (or wait for a small pullback to VWAP for better R:R).
5. **Strike: ATM** for default size. ATM+1 only if max-rupee cap forces you cheaper.
6. **Place stop:** below the swing low (CE) or above swing high (PE) of the trigger candle. Stop must be such that the rupee-loss at stop is $\leq 40\%$ of capital deployed.
7. **Set target:** +50% of premium paid; trail thereafter.

19.4 Mid-session (11:30 – 13:30 IST)

- Reliability drops here — lunch lull, lower volume.
- If you have an open position from the morning, manage it normally (trailing stop, exit on bias flip).
- Avoid **fresh entries** unless a divergence label appears AND price gives a strong reversal candle on the 3-min.
- Take a real break. Walk away from the screen. Decision fatigue is a profit-killer.

19.5 Second entry window (13:30 – 15:00 IST)

Equal-priority window with morning. Often produces the day's best follow-through trades because FII flows rebalance into the close.

1. Same workflow as 19.3.
2. Pay extra attention to **divergence labels** in this window — afternoon reversals on a strong morning trend are very common.
3. If you are already up on the day, consider sizing down to half. Protecting a green day is a discipline most traders ignore.

19.6 Closing (15:00 – 15:30 IST)

No new entries after 15:00. Square-off chaos and option premium volatility make late entries unreliable.

1. If you have an open position, exit by 15:15 IST regardless of P&L.
2. Never carry intraday signals overnight — theta decay alone will eat your edge by morning.
3. Note the final cloud colour and bias — this informs tomorrow's expected open behaviour.

19.7 Post-market review (after 15:30)

1. Open the CSV report from the paper-test module (or your manual trade log).
2. For each signal that fired, mark: was it a winner, loser, or did you skip the entry?
3. For each **missed** winner, identify why — was it a gate-failure (filter rejected), a hesitation, or a divergence you didn't act on?
4. For each **loser**, ask: did all three gates actually pass cleanly, or did you force an entry on a marginal signal?

5. Update a journal with: date, signals fired, entries taken, P&L, and one sentence on lesson learned.

19.8 The 3-minute decision flow (lamine this)

Step	Question	If YES	If NO
1	Is bias Strong Bullish or Bearish?	Go to step 2	Wait. Don't trade.
2	Does the cloud colour agree?	Go to step 3	Wait — likely choppy.
3	Is the time inside 09:30–11:30 or 13:30–15:00?	Go to step 4	Halve size or skip.
4	Did the 3-min trigger candle close on the correct side of VWAP?	Go to step 5	Wait for trigger.
5	Will the trade cost $\leq$ ₹15,000 at ATM?	Enter ATM	Use ATM+1 (cheaper) or skip.
6	Is your stop $\leq$ 40% of capital deployed?	Place order	Tighten stop or pass.

19.9 Common mistakes to avoid

Mistake	Consequence	Fix
Entering on plain "Bullish/Bearish" (not Strong)	~50% hit rate, theta bleed eats edge	Wait for Strong only, especially in first 10 sessions
Ignoring the VWAP gate	Trading divergent setups blindly → whipsaw	Always wait for price agreement
Averaging down on a losing PE/CE	Catastrophic loss when option goes to zero	Never average. Cut at stop. New trade if bias flips.
Increasing size after a loss	Revenge trading — classic blow-up	Halve size after any loss for the rest of day
Holding past 15:15	Theta decay overnight + gap risk	Hard force-flat at 15:15 IST
Trading every signal	Overtrading; commissions and slippage compound	Cap at 3 trades per day maximum

19.10 Building conviction — the 10-session protocol

- Sessions 1–3:** Run the paper-test module only. No live trades. Just observe and journal what signals fire and how they would have performed.
- Sessions 4–6:** Continue paper-testing. Begin marking each Strong signal on the chart in real time and writing what you *would* have done before checking the outcome.
- Sessions 7–10:** If the paper hit-rate is $> 55\%$ and average R:R > 1.3 , take live trades at **quarter** size (₹3,750 cap) on Strong signals only.

4. **Sessions 11+:** Scale to half size. Full size only after 30 sessions of consistent journal entries showing positive expectancy.

Discipline beats accuracy. An indicator with 55% accuracy used with strict rules outperforms an indicator with 70% accuracy used carelessly. The workflow above is the value — the indicator is just the trigger.

— End of document —

This indicator is a discretionary aid, not investment advice. Trade at your own risk.
